

Higgs Mass, CP Violation and Phase Transition in the MSSM

Koichi Funakubo¹

Abstract

The effective potential in the MSSM at the one-loop level is used to evaluate masses of the neutral Higgs scalars and to study finite-temperature phase transition. The CP violation in the Higgs sector, which is induced by the spontaneous mechanism or by the complex parameters in the MSSM through radiative corrections, is determined at zero and finite temperatures.

1 Introduction

The scenario of electroweak baryogenesis[1] requires that the electroweak phase transition (EWPT) to be of first order and that CP violation is effective at that transition temperature. The EWPT is of first order only with too light Higgs boson in the minimal standard model[2, 3], and it is argued that CP violation in the CKM matrix cannot generate sufficient baryon asymmetry. Both the requirements, however, will be fulfilled by some extension of the standard model. The minimal supersymmetric standard model (MSSM) is one of promising candidates. When some of the scalar partners of the quarks and leptons are light enough, the EWPT becomes such a strongly first-order phase transition that the sphaleron process decouples just after it with acceptable mass of the lightest Higgs scalar[4]. Although the masses of the Higgs bosons in the MSSM are constrained by some tree-level relations, they receive large radiative corrections from the top quark and squarks[5]. This may broaden a window for successful baryogenesis by the MSSM.

The MSSM has many sources of CP violations, in addition to the KM phase, such as the relative phases of the complex parameters μ , the gaugino mass parameters and scalar trilinear couplings, which are effective to generate the baryon asymmetry[6]. Besides these complex phases, the relative phase of the expectation values of the two Higgs doublets could induce the source of baryon number[7]. This phase might be induced by radiative and finite-temperature effects near the transition temperature[8] or dynamically generated near the bubble wall created at the EWPT, which we call *transitional CP violation*[9]. This mechanism has been examined dynamically by solving equations of motion for the classical Higgs fields connecting the broken and symmetric phases. Then the potential for the fields are given by the effective potential at the transition temperature, which are approximated by a gauge-invariant polynomial whose coefficients are given by the effective parameters at that temperature[10]. It was shown that the contributions from charginos and neutralinos are important to trigger the CP violation in the intermediate region. These analyses contain undetermined parameters such as the transition temperature, thickness and velocity of the bubble wall, expectation values of the Higgs fields and the magnitude of explicit CP violation at the transition temperature. These quantities should be determined by the parameters in the MSSM.

Now one of our main concerns is whether the EWPT in the MSSM is of first order strong enough for the sphaleron process to decouple after it, with acceptable masses of Higgs bosons. Recent study of the two-loop resummed effective potential at finite temperature suggests that the EWPT is strong enough for $2 \lesssim \tan\beta \lesssim 4$, $m_A \gtrsim 120\text{GeV}$ and a light Higgs with $m_h \lesssim 85\text{GeV}$ [11]. This and the previous analyses based on the one-loop resummed potential did not include the contributions from the charginos and

neutralinos. For the parameters which admit the strongly first-order EWPT, we must examine whether efficient CP violation exists at the transition temperature. The effective potentials used in the previous study of the phase transition were functions of only the CP -conserving order parameters, so that they could not evaluate CP violation in the Higgs sector at the EWPT.

In this paper, we use the effective potential in the MSSM, which includes one-loop corrections from the top quark, top squarks, gauge bosons, charginos and neutralinos, to evaluate the masses of the neutral Higgs bosons and to examine strength of the EWPT. The masses are approximated by the eigenvalues of the matrix whose elements are given by the second derivatives of the effective potential evaluated at the vacuum at zero temperature. Although the mass formulas for the neutral Higgs bosons have been found by fully-contained one-loop calculations[12] and by two-loop calculations[13], we adopt this method for self-containedness. Without CP violation, the minimum of the effective potential is parameterized by the absolute value and the ratio of the VEVs of the two Higgs doublets. Extending the effective potential to include the CP -violating order parameter and employing a numerical method to search a minimum of it, we find the magnitude of induced CP violation through radiative corrections from the superparticles when some of the parameters are complex-valued. To find the transition temperature T_C and the magnitude of the VEVs of the Higgs fields at T_C , we numerically calculate the effective potential without use of the high-temperature expansion[14], and use the same numerical method as in zero-temperature case to search a minimum of the effective potential. CP violation in the Higgs sector will provide a boundary condition for the equations which dynamically determines the profile of the bubble wall[15].

This paper is organized as follows. In Section 2, we derive formulas for the neutral Higgs boson masses in the MSSM in the absence of CP violation and a numerical method is introduced which can be applied to the case with CP violation. The method is extended to the effective potential at finite temperature in Section 3. Numerical results on the masses of the Higgs scalars and transition temperature and strength of the EWPT are summarized in Section 4. Section 5 is dedicated to concluding remarks. The formulas for the derivatives of the effective potential are summarized in the Appendix.

2 Higgs Boson Masses

If we write the VEVs of the two Higgs doubles as φ_d and φ_u , the tree-level potential is given by

$$V_0 = m_1^2 \varphi_d^\dagger \varphi_d + m_2^2 \varphi_u^\dagger \varphi_u + (\mu B \varphi_u \varphi_d + \text{h.c.})$$

$$+ \frac{g_2^2 + g_1^2}{8} (\varphi_d^\dagger \varphi_d - \varphi_u^\dagger \varphi_u)^2 + \frac{g_2^2}{2} (\varphi_d^\dagger \varphi_d) (\varphi_u^\dagger \varphi_u), \quad (2.1)$$

where we take $m_3^2 \equiv \mu B$ to be real and positive by phase convention of the fields. Now we parameterize the VEVs as¹

$$\varphi_d = \frac{1}{\sqrt{2}} \begin{pmatrix} v_1 + iv_4 \\ 0 \end{pmatrix}, \quad \varphi_u = \frac{1}{\sqrt{2}} \begin{pmatrix} 0 \\ v_2 + iv_3 \end{pmatrix}. \quad (2.2)$$

Then the tree-level potential is expressed as

$$V_0 = \frac{1}{2} m_1^2 (v_1^2 + v_4^2) + \frac{1}{2} m_2^2 (v_2^2 + v_3^2) - m_3^2 (v_1 v_2 - v_3 v_4) + \frac{g_2^2 + g_1^2}{32} (v_1^2 + v_4^2 - v_2^2 - v_3^2)^2. \quad (2.3)$$

The minimum of this potential is given by

$$v_1 = v_0 \cos \beta, \quad v_2 = v_0 \sin \beta, \quad v_3 = v_4 = 0, \quad (2.4)$$

with

$$m_1^2 = m_3^2 \tan \beta - \frac{1}{2} m_Z^2 \cos(2\beta), \quad m_2^2 = m_3^2 \cot \beta + \frac{1}{2} m_Z^2 \cos(2\beta), \quad (2.5)$$

so that CP is conserved. The effective potential at the one-loop level is given by

$$V_{\text{eff}}(\mathbf{v}) = V_0(\mathbf{v}) + \Delta V(\mathbf{v}), \quad (2.6)$$

where

$$\Delta V(\mathbf{v}) = \Delta_g V(\mathbf{v}) + \Delta_t V(\mathbf{v}) + \Delta_{\bar{t}} V(\mathbf{v}) + \Delta_{\chi^\pm} V(\mathbf{v}) + \Delta_{\chi^0} V(\mathbf{v}) \quad (2.7)$$

is the sum of the one-loop corrections. Each term is given as follows.

$$\Delta_g V(\mathbf{v}) = 3 \cdot 2F(m_W^2(\mathbf{v})) + 3F(m_Z^2(\mathbf{v})), \quad (2.8)$$

$$\Delta_t V(\mathbf{v}) = -4 \cdot 3 \cdot F(m_t^2(\mathbf{v})), \quad (2.9)$$

$$\Delta_{\bar{t}} V(\mathbf{v}) = 2 \cdot 3 \cdot \sum_{a=1,2} F(m_{t_a}^2(\mathbf{v})), \quad (2.10)$$

$$\Delta_{\chi^\pm} V(\mathbf{v}) = -4 \sum_{a=1,2} F(m_{\chi_a^\pm}^2(\mathbf{v})), \quad (2.11)$$

$$\Delta_{\chi^0} V(\mathbf{v}) = -2 \sum_{a=1,2,3,4} F(m_{\chi_a^0}^2(\mathbf{v})), \quad (2.12)$$

where

$$F(m^2) \equiv \frac{m^4}{64\pi^2} \left(\log \frac{m^2}{M_{\text{ren}}^2} - \frac{3}{2} \right), \quad (2.13)$$

¹The order parameter v_4 can be eliminated by the gauge transformation. So we shall set $v_4 = 0$ except when we numerically calculate the Higgs boson masses in the presence of CP violation.

which was renormalized by the $\overline{\text{DR}}$ -scheme. The renormalization scale M_{ren} will be taken to be the weak scale. The masses-squared in (2.8) and (2.9) are given by

$$\begin{aligned} m_W^2(\mathbf{v}) &= \frac{g_2^2}{4}(v_1^2 + v_2^2 + v_3^2 + v_4^2), & m_Z^2(\mathbf{v}) &= \frac{g_2^2 + g_1^2}{4}(v_1^2 + v_2^2 + v_3^2 + v_4^2), \\ m_t^2(\mathbf{v}) &= \frac{y_t^2}{2}(v_2^2 + v_3^2). \end{aligned} \quad (2.14)$$

$m_{\tilde{t}_a}^2(\mathbf{v})$ in (2.10) are the eigenvalues of the matrix

$$M_{\tilde{t}}^2 = \begin{pmatrix} m_{\tilde{t}_L}^2 + m_t^2(\mathbf{v}) + \frac{3g_2^2 - g_1^2}{12}(v_1^2 - v_2^2 - v_3^2 + v_4^2) & \frac{y_t}{\sqrt{2}}[\mu(v_1 + iv_4) + A_t(v_2 - iv_3)] \\ \frac{y_t}{\sqrt{2}}[\mu(v_1 - iv_4) + A_t(v_2 + iv_3)] & m_{\tilde{t}_R}^2 + m_t^2(\mathbf{v}) + \frac{g_2^2}{6}(v_1^2 - v_2^2 - v_3^2 + v_4^2) \end{pmatrix}. \quad (2.15)$$

$m_{\chi_a^\pm}^2(\mathbf{v})$ in (2.11) are the eigenvalues of the matrix $M_{\chi^\pm}^\dagger M_{\chi^\pm}$ with

$$M_{\chi^\pm} = \begin{pmatrix} M_2 & -\frac{i}{\sqrt{2}}g_2(v_2 - iv_3) \\ -\frac{i}{\sqrt{2}}g_2(v_1 - iv_4) & -\mu \end{pmatrix}, \quad (2.16)$$

and $m_{\chi_a^0}^2(\mathbf{v})$ in (2.12) are the eigenvalues of the matrix $M_{\chi^0}^\dagger M_{\chi^0}$ with

$$M_{\chi^0} = \begin{pmatrix} M_2 & 0 & -\frac{i}{2}g_2(v_1 - iv_4) & \frac{i}{2}g_2(v_2 - iv_3) \\ 0 & M_1 & \frac{i}{2}g_1(v_1 - iv_4) & -\frac{i}{2}g_1(v_2 - iv_3) \\ -\frac{i}{2}g_2v_1(v_1 - iv_4) & \frac{i}{2}g_1(v_1 - iv_4) & 0 & \mu \\ \frac{i}{2}g_2(v_2 - iv_3) & -\frac{i}{2}g_1(v_2 - iv_3) & \mu & 0 \end{pmatrix}. \quad (2.17)$$

In general, μ , A_t , M_2 and M_1 are complex-valued but we assume them to be real until we discuss CP violation.

The minimization conditions of the effective potential relate the mass parameters in the Higgs potential to the VEVs of the Higgs fields:

$$\begin{aligned} m_1^2 &= m_3^2 \tan \beta - \frac{1}{2}m_Z^2 \cos(2\beta) - \frac{1}{v_1} \frac{\partial \Delta V(\mathbf{v})}{\partial v_1}, \\ m_2^2 &= m_3^2 \cot \beta + \frac{1}{2}m_Z^2 \cos(2\beta) - \frac{1}{v_2} \frac{\partial \Delta V(\mathbf{v})}{\partial v_2}, \end{aligned} \quad (2.18)$$

which are used to eliminate m_1^2 and m_2^2 in favor of $v_0 \equiv |\mathbf{v}|$ and $\tan \beta = v_2/v_1$. These are equivalent to the tadpole conditions[12]. The masses of the CP -even Higgs bosons are the eigenvalues of the matrix

$$\mathcal{M}_h^2 \equiv \begin{pmatrix} \frac{\partial^2 V_{\text{eff}}(\mathbf{v})}{\partial v_1^2} & \frac{\partial^2 V_{\text{eff}}(\mathbf{v})}{\partial v_1 \partial v_2} \\ \frac{\partial^2 V_{\text{eff}}(\mathbf{v})}{\partial v_1 \partial v_2} & \frac{\partial^2 V_{\text{eff}}(\mathbf{v})}{\partial v_2^2} \end{pmatrix}, \quad (2.19)$$

where the derivatives should be evaluated at the vacuum. The mass of the CP -odd scalar is given by

$$m_A^2 = \frac{1}{\cos^2 \beta} \frac{\partial^2 V_{\text{eff}}(\mathbf{v})}{\partial v_3^2}. \quad (2.20)$$

By use of (2.18), the second derivatives evaluated at the vacuum are reduced to

$$\frac{\partial^2 V_{\text{eff}}(\mathbf{v})}{\partial v_1^2} = m_3^2 \tan \beta + m_Z^2 \cos^2 \beta + v_1 \frac{\partial}{\partial v_1} \left(\frac{1}{v_1} \frac{\partial \Delta V(\mathbf{v})}{\partial v_1} \right), \quad (2.21)$$

$$\frac{\partial^2 V_{\text{eff}}(\mathbf{v})}{\partial v_2^2} = m_3^2 \cot \beta + m_Z^2 \sin^2 \beta + v_2 \frac{\partial}{\partial v_2} \left(\frac{1}{v_2} \frac{\partial \Delta V(\mathbf{v})}{\partial v_2} \right), \quad (2.22)$$

$$\frac{\partial^2 V_{\text{eff}}(\mathbf{v})}{\partial v_1 \partial v_2} = -m_3^2 - m_Z^2 \sin \beta \cos \beta + \frac{\partial^2 \Delta V(\mathbf{v})}{\partial v_1 \partial v_2}, \quad (2.23)$$

$$\frac{\partial^2 V_{\text{eff}}(\mathbf{v})}{\partial v_3^2} = m_3^2 \cot \beta - \frac{1}{v_2} \frac{\partial \Delta V(\mathbf{v})}{\partial v_2} + \frac{\partial^2 \Delta V(\mathbf{v})}{\partial v_3^2}. \quad (2.24)$$

The expressions of the derivatives of $\Delta V(\mathbf{v})$ are summarized in the Appendix.

In addition to the evaluation of the masses by use of these formulas, we adopt a fully numerical method. In this method, the effective potential defined by (2.6) is calculated at every $\mathbf{v} = (v_1, v_2, v_3, v_4)$, where the mass eigenvalues are evaluated numerically. For a given set of $(v_0, \tan \beta)$ and m_3^2 , the mass parameters in the Higgs potential are determined by (2.18). The minimum of the effective potential is searched by use of the downhill simplex algorithm[16] starting from a randomly generated simplex in the restricted space of (v_1, v_2, v_3) with $v_4 = 0$. Once the minimum is found, the second derivatives of the effective potential with respect to (v_1, v_2, v_3, v_4) are numerically evaluated. We have checked, in the absence of CP violation, that the minimum coincides with the prescribed $(v_0, \tan \beta)$ and that the four-by-four matrix of the second derivatives is completely divided into to the two sectors of CP eigenmodes and the eigenvalues coincides with those obtained by use of the formulas above. This numerical method can be applied to the case with CP violation. In the presence of CP violation such as the relative phases of complex parameters, CP -violating order parameter v_3 is induced and the CP eigenstates of the Higgs sector mix to make the mass eigenstates.

3 Finite-Temperature Effective Potential

At finite temperatures, the one-loop corrections in (2.8)–(2.12) are modified to include the finite-temperature effects:

$$\Delta_g V(\mathbf{v}; T) = \Delta_g V(\mathbf{v}) + \frac{T^4}{2\pi^2} \left[6I_B \left(\frac{m_W^2(\mathbf{v})}{T^2} \right) + 3I_B \left(\frac{m_Z^2(\mathbf{v})}{T^2} \right) \right], \quad (3.1)$$

$$\Delta_t V(\mathbf{v}; T) = \Delta_t V(\mathbf{v}; T) - 12 \cdot \frac{T^4}{2\pi^2} I_F \left(\frac{m_t^2(\mathbf{v})}{T^2} \right), \quad (3.2)$$

$$\Delta_{\tilde{t}} V(\mathbf{v}; T) = \Delta_{\tilde{t}} V(\mathbf{v}) + 6 \cdot \frac{T^4}{2\pi^2} \sum_{a=1,2} I_B \left(\frac{m_{\tilde{t}_a}^2(\mathbf{v})}{T^2} \right), \quad (3.3)$$

$$\Delta_{\chi^\pm} V(\mathbf{v}; T) = \Delta_{\chi^\pm} V(\mathbf{v}) - 4 \cdot \frac{T^4}{2\pi^2} \sum_{a=1,2} I_F \left(\frac{m_{\chi_a^\pm}^2(\mathbf{v})}{T^2} \right), \quad (3.4)$$

$$\Delta_{\chi^0} V(\mathbf{v}; T) = \Delta_{\chi^0} V(\mathbf{v}) - 2 \cdot \frac{T^4}{2\pi^2} \sum_{a=1,2,3,4} I_F \left(\frac{m_{\chi_a^0}^2(\mathbf{v})}{T^2} \right), \quad (3.5)$$

where the functions $I_B(a^2)$ and $I_F(a^2)$ are defined by

$$I_{B,F}(a^2) = \int_0^\infty dx \, x^2 \log \left(1 \mp e^{-\sqrt{x^2+a^2}} \right). \quad (3.6)$$

The effective potential at finite temperature is calculated at each $\mathbf{v}$ by numerically evaluating the mass-squared eigenvalues and inserting them into the expressions (3.1)–(3.5). The integrals defined in (3.6) are numerically calculated without use of the high-temperature expansions[14].

For a given set of parameters, the minimum of the effective potential is searched at various temperatures by the method stated in the previous section. Near the transition temperature, several numbers of starting simplexes are generated and the minimum reached starting from each simplex is found. The temperature at which two degenerate minima are found is defined to be the transition temperature T_C of the first-order EWPT. Then we examine whether the condition is satisfied for the sphaleron process to decouple just after the EWPT[17]

$$\frac{v_C}{T_C} = \lim_{T \uparrow T_C} \frac{|\mathbf{v}(T)|}{T} > 1. \quad (3.7)$$

If $v_C = 0$, the EWPT is of second order. We executed this minimum search for various sets of parameters to find the order of the EWPT and T_C , and measured v_C and $\tan \beta$ at T_C when the EWPT is of first order.

4 Numerical Results

4.1 CP -conserving case

Among many parameters in the MSSM, the mass parameters m_1^2 and m_2^2 in the Higgs potential are determined by (2.18) in the absence of CP violation. Throughout this paper, we take $v_0 = 246\text{GeV}$, $m_W = 80.3\text{GeV}$, $m_Z = 91.2\text{GeV}$ and $m_t = 175\text{GeV}$. The rest of the parameters are m_3^2 , $\tan \beta$, μ , A_t , $m_{\tilde{t}_L}$, $m_{\tilde{t}_R}$, M_2 and M_1 . For definiteness, we take $M_2 = M_1$, $m_{\tilde{t}_L} = 400\text{GeV}$ and $A_t = 10\text{GeV}$.

Before presenting the numerical results on the Higgs masses and CP violation, we note that the contributions from the charginos and neutralinos are not negligible compared to those from the top quarks and squarks. For example, consider the contributions to the first

Table 1: Contributions to the equations relating the mass parameters in the Higgs potential to the VEVs of the Higgs fields from the stop and charginos. $(\tan \beta, \mu) = (2, -20\text{GeV})$ and $(\tan \beta, \mu) = (5, -50\text{GeV})$ correspond to the zero stop mixing case.

$\tan \beta$	$\mu(\text{GeV})$	$m_{\tilde{t}_R}(\text{GeV})$	$\Delta_{\tilde{t}} m_1^2(\text{GeV}^2)$	$\Delta_{\tilde{t}} m_2^2(\text{GeV}^2)$	$\Delta_{\chi^\pm} m_1^2(\text{GeV}^2)$	$\Delta_{\chi^\pm} m_2^2(\text{GeV}^2)$
2	-20	0	-1.323×10^3	-7.402×10^3	5.723×10^2	6.967×10^2
2	-20	300	-1.596×10^3	-1.131×10^4	5.723×10^2	6.967×10^2
2	-300	0	-5.900×10^3	-7.482×10^3	-4.799×10^3	1.263×10^3
2	-300	300	-7.089×10^3	-1.131×10^4	-4.799×10^3	1.263×10^3
5	-50	0	-1.302×10^3	-5.831×10^3	8.050×10^1	7.293×10^2
5	-50	300	-1.573×10^3	-9.017×10^3	8.050×10^1	7.293×10^2
5	-300	0	-4.688×10^3	-5.824×10^3	-3.769×10^3	1.628×10^3
5	-300	300	-5.640×10^3	-8.999×10^3	-3.769×10^3	1.628×10^3

derivatives appearing in (2.18), which have the form of $\frac{1}{v_i} \frac{\partial m^2}{\partial v_i} F'(m^2)$. The contributions from the gauge bosons is smaller than those from the top quark, since for $\tan \beta = 5$

$$\frac{1}{v_2} \frac{\partial m_t^2(\mathbf{v})}{\partial v_2} = \frac{2m_t^2}{v_0^2 \sin^2 \beta} = y_t^2 \simeq 1.0526, \quad \frac{1}{v_i} \frac{\partial m_W^2(\mathbf{v})}{\partial v_i} = \frac{g_2^2}{2} \simeq 0.2131, \quad (4.1)$$

which multiply $-12F'(m_t^2)$ and $6F'(m_W^2)$, respectively. For the case of the stop and charginos, these factors are replaced with (A.13) and (A.22) or (A.23), which depend not only on the couplings but also on μ , $\tan \beta$ and the soft-SUSY-breaking masses. When $m_{\tilde{t}}^2$ is the same order as $m_{\chi^\pm}$, there is no reason for the stop contribution to become much larger than the chargino contributions. Now let us denote

$$\begin{aligned} \Delta_{\tilde{t}} m_1^2 &= -\frac{1}{v_1} \frac{\partial \Delta_{\tilde{t}} V(\mathbf{v})}{\partial v_1}, & \Delta_{\tilde{t}} m_2^2 &= -\frac{1}{v_2} \frac{\partial \Delta_{\tilde{t}} V(\mathbf{v})}{\partial v_2}, \\ \Delta_{\chi^\pm} m_1^2 &= -\frac{1}{v_1} \frac{\partial \Delta_{\chi^\pm} V(\mathbf{v})}{\partial v_1}, & \Delta_{\chi^\pm} m_2^2 &= -\frac{1}{v_2} \frac{\partial \Delta_{\chi^\pm} V(\mathbf{v})}{\partial v_2}, \end{aligned} \quad (4.2)$$

and calculate them for $M_2 = 300\text{GeV}$. Several numerical values are presented in Table 1. This suggests that when $M_2 \sim |\mu| \sim m_{\tilde{t}_L}$, $\Delta_{\tilde{t}} m_1^2$ and $\Delta_{\tilde{t}} m_2^2$ are of the same order as $\Delta_{\chi^\pm} m_1^2$ and $\Delta_{\chi^\pm} m_2^2$. As seen from (A.15) and (A.25), the factors multiplying $F'(m^2)$, which are the couplings squared in the case of the quarks and gauge bosons, are corrected by $n_{\tilde{t}}^{(1)}/R_{\tilde{t}}$, $n_{\chi}^{(1)}/R_{\chi}$ and $n_{\chi}^{(2)}/R_{\chi}$ for the stops and charginos, respectively. For the case of $\tan \beta = 5$, $\mu = -300\text{GeV}$ and $m_{\tilde{t}_R} = 0$ in Table 1, $n_{\tilde{t}}^{(1)}/R_{\tilde{t}} \simeq 0.53$ while $n_{\chi}^{(1)}/R_{\chi} \simeq -13.4$ and $n_{\chi}^{(2)}/R_{\chi} \simeq 2.85$, which are large enough to compensate the difference between the gauge and Yukawa coupling constants. As for the neutralino, although its contributions cannot be expressed in a compact form as (A.11), it is natural to expect the neutralino contributions to be the same order as the chargino, as far as $M_2 \sim M_1$. For $\tan \beta = 5$

Figure 1: Contour plots of the mass of the lighter chargino as function of the MSSM parameters M_2 and μ for $\tan\beta = 2, 5$ and 20 , respectively. All the mass units are GeV.

and $\mu = -300\text{GeV}$, we have

$$\frac{1}{v_1} \frac{\partial \Delta_{\chi^0} V(\mathbf{v})}{\partial v_1} = 2.374 \times 10^3 \text{GeV}^2, \quad \frac{1}{v_2} \frac{\partial \Delta_{\chi^0} V(\mathbf{v})}{\partial v_2} = -1.013 \times 10^3 \text{GeV}^2, \quad (4.3)$$

which are the same order as the chargino contributions. As for the second derivatives, we find that the contributions from the charginos and neutralinos are the same order as those from the stops for the parameters we adopted in the numerical analyses. We also observed that if we omit $\Delta_{\chi^\pm} V(\mathbf{v})$ and $\Delta_{\chi^0} V(\mathbf{v})$ to determine m_1^2 and m_2^2 in favor of v_0 and $\tan\beta$ by (2.18), the numerical method to search the minimum results in a different point in (v_1, v_2) -plane from $(v_0 \cos\beta, v_0 \sin\beta)$ with a deviation of about 5% for $\tan\beta > 10$ and of about 70% for $\tan\beta \lesssim 2$. Thus, as long as the soft mass parameters M_2 , M_1 and $m_{\tilde{t}_{L,R}}$ are of the same order, the contributions from the charginos and neutralinos are comparable to those from the top squarks.

Now we show results on the masses of the neutral Higgs bosons. We examine dependence of the mass of the lighter scalar m_h on the pseudoscalar mass m_A and $M_2 = M_1$. In practice, we calculate m_h and m_A as functions of (m_3^2, M_2) for a fixed set of $(\tan\beta, \mu, m_{\tilde{t}_R})$ and make a contour plot of m_h in (M_2, m_A) -plane. The mass of the lighter chargino $m_{\chi_1^\pm}$ is constrained to be $m_{\chi_1^\pm} > 65.7\text{GeV}$ [18], which restricts μ and M_2 . According to the tree-level mass formula (A.21), the mass is plotted as a function of M_2 and μ in Fig. 1. This shows that the lower limit is satisfied for the whole range of M_2 we studied, if we take $|\mu| \gtrsim 100\text{GeV}$. The limits on the masses of the lighter Higgs scalar and pseudoscalar are now $m_h > 62.5\text{GeV}$ and $m_A > 62.5\text{GeV}$ [18], although more stringent bounds are reported $m_h \gtrsim 75\text{GeV}$ [19]. The results on m_h are plotted in Figs. 2 and 3 for $\tan\beta = 2$, in Figs. 4 and 5 and in Figs. 6 and 7. We also calculated m_h for $|\mu| = 100\text{GeV}$ and 200GeV and found that m_h behaves in the same manner as the case of $|\mu| = 300\text{GeV}$ but its value

Figure 2: Contour plots of m_h as function of the MSSM parameters M_2 and m_A for $\tan \beta = 2$, $\mu = -300\text{GeV}$ and $m_{\tilde{t}_R} = 0, 100\text{GeV}$ and 200GeV , respectively. All the mass units are GeV.

Figure 3: The same as Fig. 2 but for $\tan \beta = 2$, $\mu = 300\text{GeV}$ and $m_{\tilde{t}_R} = 0, 100\text{GeV}$ and 200GeV , respectively. All the mass units are GeV.

becomes a bit smaller for smaller $|\mu|$. For $\mu = 300\text{GeV}$, in the blank region at small m_A and large M_2 region, the point $\mathbf{v} = (v_0 \cos \beta, v_0 \sin \beta)$ is not a local minimum but a saddle point. This region is broader for larger $\tan \beta$, which corresponds to smaller top Yukawa coupling. This is because for larger M_2 , the contributions from the charginos and neutralinos to the effective potential, which are negative, dominate over the bosonic contributions and make the vacuum unstable. For $\tan \beta = 2$, the experimental bound on m_h is satisfied for $m_A \gtrsim 200 - 300\text{GeV}$, depending on μ and M_2 . For $\tan \beta \geq 5$, it is satisfied for $m_A \gtrsim 100\text{GeV}$.

At finite temperatures, the minimum of the effective potential differs from that at zero temperature. What we concern here are the order of the EWPT and transition temperature T_C , at which two minima of the effective potential degenerate, and the location of the minimum at T_C when it is of first order. These are important ingredients for the

Figure 4: The same as Fig. 2 but for $\tan\beta = 5$, $\mu = -300\text{GeV}$ and $m_{\tilde{t}_R} = 0, 100\text{GeV}$ and 200GeV , respectively. All the mass units are GeV.

Figure 5: The same as Fig. 2 but for $\tan\beta = 5$, $\mu = 300\text{GeV}$ and $m_{\tilde{t}_R} = 0, 100\text{GeV}$ and 200GeV , respectively. All the mass units are GeV.

Figure 6: The same as Fig. 2 but for $\tan\beta = 20$, $\mu = -300\text{GeV}$ and $m_{\tilde{t}_R} = 0, 100\text{GeV}$ and 200GeV , respectively. All the mass units are GeV.

Figure 7: The same as Fig. 2 but for $\tan\beta = 20$, $\mu = 300\text{GeV}$ and $m_{\tilde{t}_R} = 0, 100\text{GeV}$ and 200GeV , respectively. All the mass units are GeV.

electroweak baryogenesis. For definiteness, we take $\mu = -300\text{GeV}$, $M_2 = M_1 = 350\text{GeV}$, $m_{\tilde{t}_L} = 400\text{GeV}$ and $A_t = 10\text{GeV}$. By use of the numerical method explained in the previous section, we search the minimum of the effective potential at various temperatures to find the transition temperature. This analysis is done for $\tan\beta = 2, 5$ and 20 with various $m_{\tilde{t}_R} \geq 0$ and two values of m_3^2 being tuned so that $m_h \simeq 62.5\text{GeV}$ and $m_h \simeq 80\text{GeV}$, respectively, for $m_{\tilde{t}_R} = 0$.²

For $\tan\beta = 2$ and small $m_{\tilde{t}_R}$, it is difficult to have m_h larger than 70GeV as seen from Fig. 2. We have adopted $m_3^2 = 2.5 \times 10^4\text{GeV}^2$, for which $m_h \simeq 62.5\text{GeV}$ when $m_{\tilde{t}_R} = 0$. Dependences of v_C/T_C , $\tan\beta(T_C)$ and the masses on $m_{\tilde{t}_R}$ are plotted in Fig. 8. The condition for the sphaleron decoupling after the EWPT (3.7) is satisfied for $m_{\tilde{t}_R} \lesssim 75\text{GeV}$, for which $m_h \lesssim 64\text{GeV}$ and $m_A \simeq 239\text{GeV}$. The transition temperature varies from $T_C = 77.3\text{GeV}$ ($m_{\tilde{t}_R} = 0$) to 88.7GeV ($m_{\tilde{t}_R} = 120\text{GeV}$) monotonously. $\tan\beta$ at T_C is almost independent of $m_{\tilde{t}_R}$ and remains to be the zero temperature value.

For $\tan\beta = 5$, we have taken $m_3^2 = 3050\text{GeV}^2$ and 4624GeV^2 , which correspond to $m_h \simeq 62.5\text{GeV}$ and 80GeV , respectively. T_C is monotonously decreasing with respect to $m_{\tilde{t}_R}$ and for the former case, $93.2\text{GeV} \leq T_C \leq 100.5\text{GeV}$, while $93.0\text{GeV} \leq T_C \leq 100.2\text{GeV}$ for the latter case. Dependence of T_C on m_3^2 , so that on m_A , appears to be weak. v_C/T_C , $\tan\beta(T_C)$ and the masses are plotted in Fig. 9 and Fig. 10. The condition (3.7) is satisfied for $m_{\tilde{t}_R} \lesssim 50\text{GeV}$. $\tan\beta$ at T_C receives finite-temperature corrections to become about 20% larger than the zero-temperature value for the case of the larger m_A .

For $\tan\beta = 20$, we adopted $m_3^2 = 2308\text{GeV}^2$ and 2440GeV^2 . Dependence of T_C on $m_{\tilde{t}_R}$ and m_3^2 is similar to the previous examples of $\tan\beta = 5$. Now $97.2\text{GeV} \leq T_C \leq 104.5\text{GeV}$ for both choices of m_3^2 . v_C/T_C , $\tan\beta(T_C)$ and the masses are plotted in Fig. 11 and

²For $\tan\beta = 2$ and the rest of the parameters given above, m_h cannot be so large as 70GeV . So the results are presented only for $m_h \simeq 62.5\text{GeV}$.

Figure 8: Dependence of v_c/T_c (solid curve) and $\tan\beta(T_c)$ (dashed curve) on $m_{\tilde{t}_R}$ for $m_3^2 = 2.5 \times 10^4 \text{GeV}^2$. m_h (solid curve), m_A (dashed curve) and $m_{\tilde{t}_1}$ (dotted curve) are also shown for the same parameter set.

Figure 9: The same as Fig. 8 but for $\tan\beta = 5$ and $m_3^2 = 3050 \text{GeV}^2$.

Figure 10: The same as Fig. 8 but for $\tan\beta = 5$ and $m_3^2 = 4624 \text{GeV}^2$.

Figure 11: The same as Fig. 8 but for $\tan \beta = 20$ and $m_3^2 = 2308 \text{ GeV}^2$.

Figure 12: The same as Fig. 8 but for $\tan \beta = 20$ and $m_3^2 = 2440 \text{ GeV}^2$.

Fig. 12. In this case, $\tan \beta(T_C)$ drastically deviate from the zero-temperature value.

In order to determine the profile of the bubble wall created at the first-order EWPT, we must know the global structure of the effective potential at T_C . As an example, we show the contour plot of the effective potential at $T = 0$ and $T = T_C$ for the case of $\tan \beta = 5$, $m_3^2 = 4624 \text{ GeV}^2$ and $m_{\tilde{t}_R} = 0$ in Fig. 13. This shows that two degenerate minima at T_C is connected by a valley with almost constant $\tan \beta(T_C) \simeq 6$. This is also the case for the other sets of the parameters we studied. Some of the baryogenesis scenarios based on the MSSM requires that $\tan \beta$ varies spatially around the bubble wall. But this result implies that $\tan \beta$ remains to be almost constant around the wall.

4.2 CP -violating case

In the MSSM, there are many sources of CP violation other than the phase in the CKM matrix. Among them are relative phases of the complex parameters μ , A_t , M_2 and M_1 . These also induce CP violation in the Higgs sector, which is the relative phase θ of the VEVs of the two Higgs doublets. This θ together with the other CP -violating phases affect such observables as the electric dipole moment of the neutron. Hence knowledge of θ is necessary to find bounds on the phases of the complex parameters in the MSSM.

Figure 13: Contour plots of the effective potential at $T = 0$ and $T = T_C$ for $\tan \beta = 5$, $m_3^2 = 4624 \text{ GeV}^2$ and $m_{\tilde{t}_R} = 0$.

$\theta = \text{Arg}(v_2 + iv_3)$ in the gauge with $v_4 = 0$ is determined by minimizing the effective potential at $T = 0$. Even when all the parameters are real, the effective potential could have CP -violating vacuum. This is known as the spontaneous CP violation, but in the MSSM it inevitably accompanies a too light scalar[20]. We found that this is the case. Indeed if we take $\tan \beta = 5$ and $m_{\tilde{t}_R} = 0$ and tune $m_3^2 = 2113.3 \text{ GeV}^2$, the effective potential has two degenerate minima which correspond to $\theta = \pm 0.318$ and $\tan \beta = 4.917$. Then the lightest scalar mass is 12.9 GeV , which differs from any mass from the mass formulas because of large mixing of the CP eigenstates.

Now we study the effect of explicit CP violation in the complex parameters on the CP violation in the Higgs sector. As the first example, we take $\tan \beta = 5$, $m_{\tilde{t}_R} = 0$, $m_3^2 = 4624 \text{ GeV}^2$, $\mu = -300 \cdot e^{i\delta_\mu}$ and the remaining parameters are set to be the values adopted in the previous subsection. For nonzero δ_μ , θ have nonzero value and the scalar and pseudoscalar mixes to form the mass eigenstates. By the numerical method, the minimum of the effective potential were searched and the second derivatives at the minimum was evaluated to calculate the masses of the Higgs bosons, for $0 \leq \delta_\mu \leq 0.1$. Dependence of θ , $\tan \beta$ and masses of two light bosons on δ_μ is depicted in Fig. 14. Within this range of δ_μ , the derivation of the masses from the values at δ_μ is negligible. The induced θ is the same order and has the same sign as δ_μ . By linearly fitting, we find $\theta = 0.8265 \cdot \delta_\mu$. By redefining the fields, we find that the physical CP -violating phase in the mass matrices (2.15), (2.16) and (2.17) is $\delta_\mu + \theta$. Hence δ_μ enhances the magnitude of CP violation.

As a second example, we put $M_2 = M_1 = 350 \cdot e^{i\delta_2} \text{ GeV}$ and all the rest parameters are taken to be real and set to the same values as the previous example. Dependence of

Figure 14: Dependence of θ (solid curve), $\tan \beta$ (dashed curve) and Higgs masses on δ_μ .

Figure 15: Dependence of θ (solid curve), $\tan \beta$ (dashed curve) and Higgs masses on δ_2 .

θ , $\tan \beta$ and masses of two light bosons on δ_μ is shown in Fig. 15. The induced CP phase is fitted to $\theta = 0.8885 \cdot \delta_2$, which has the same sign as the original δ_2 . Since the physical CP phase in the mass matrix (2.16) is $\delta_2 + \theta$, the CP -violating phase is enhanced by the radiative corrections.

In the scenario of the electroweak baryogenesis, the CP violation around the bubble wall is a key ingredient and it is determined by solving the equations of motion with the effective potential at T_C . Then the VEVs in the two degenerate minima provide the boundary conditions to these equations. Although spontaneous CP violation at $T \simeq T_C$ could occur, it would accompany a too light scalar at zero temperature. Any way, an explicit CP violation is necessary to resolve degeneracy in energy of the CP -conjugate pair of the bubble walls, otherwise no net baryon asymmetry would survive the EWPT. For the same parameters as the zero temperature case, we plot in Fig. 16 dependences of the

Figure 16: Dependence of θ (solid curve), $\tan \beta$ (dashed curve) at $T = 92\text{GeV}$.

induced CP violating phase θ and $\tan \beta$ on the phase of the μ -parameter. The behaviors of θ and $\tan \beta$ are almost the same as those at zero temperature, but $\theta = 0.8862 \cdot \delta_\mu$.

5 Discussion

We have studied the masses of the neutral Higgs bosons and the electroweak phase transition of the MSSM by use of the one-loop effective potential. For the parameters we adopted, the contributions from the charginos and neutralinos are shown not to be negligible. We have found that the EWPT is of so strongly first order that the sphaleron process after it decouples, for $m_{\tilde{t}_R} \lesssim 75\text{GeV}$ when $\tan \beta = 2$, $m_h = 62.8\text{GeV}$ and $m_A = 239\text{GeV}$, for $m_{\tilde{t}_R} \lesssim 50\text{GeV}$ when $\tan \beta = 5$, $m_h = 62.8\text{GeV}$ and $m_A = 70\text{GeV}$, for $m_{\tilde{t}_R} \lesssim 53\text{GeV}$ when $\tan \beta = 5$, $m_h = 80\text{GeV}$ and $m_A = 114\text{GeV}$, for $m_{\tilde{t}_R} \lesssim 46.7\text{GeV}$ when $\tan \beta = 20$, $m_h = 62.7\text{GeV}$ and $m_A = 62.6\text{GeV}$, and for $m_{\tilde{t}_R} \lesssim 46.8\text{GeV}$ when $\tan \beta = 20$, $m_h = 80\text{GeV}$ and $m_A = 81\text{GeV}$. These bounds on $m_{\tilde{t}_R}$ almost correspond to a bound on the lighter stop mass $m_{\tilde{t}_1} \leq m_t$. For the parameters which permit strongly first-order EWPT, we have investigated $\tan \beta$ at the transition temperature. It receives larger temperature-corrections for larger $\tan \beta$ at zero temperature, which corresponds to smaller Yukawa coupling of the top quark. This suggests importance of finite-temperature contributions from the particles other than the top quark and squarks. We also studied CP violation in the Higgs sector, which is characterized by the relative phase θ of the expectation values of the two Higgs doublets. As is well known, the spontaneous mechanism to generate θ accompanies a too light scalar. An explicit CP violation in the complex parameters induces θ of the same order and sign as itself, through radiative and finite-temperature corrections. This implies that the physical phases in the mass matrices of the

chargino, neutralino and stop are enhanced by the complex phases which are originally contained in these matrices. Hence one must take this effect into account to find bounds on the parameters in the MSSM obtained from such data as the neutron EDM.

Some of the mechanism of electroweak baryogenesis in the MSSM requires $\tan\beta$ to vary spatially. But at the transition temperature, it stays almost constant at $\tan\beta(T_C)$. Then viable scenarios of the electroweak baryogenesis rely on spatially varying θ and/or $|\boldsymbol{v}|$ in the presence explicit CP violation. The spatial dependence of θ and $|\boldsymbol{v}|$ around the bubble wall created at the EWPT is examined in [15]. The values of these variables in the broken phase at T_C obtained here will serve as the boundary conditions to the dynamical equations for $(\theta(x), |\boldsymbol{v}(x)|)$. These functions in the MSSM will be studied elsewhere[21].

In this paper, we extensively used the one-loop effective potential for self-containedness. Extension to the two-loop resummed potential would be straightforward. The two-loop resummed potential without the contributions from the charginos and neutralinos yields strongly first-order EWPT for a wider range of parameters than the corresponding one-loop potential[11]. We expect that if the higher-order effects are taken into account, the effective potential including the contributions from all the particles in the MSSM will provide strongly first-order EWPT for a broader region in the parameter space than that investigated here.

A Derivatives of the Effective Potential

We present the formulas for the first and second derivatives of the effective potential evaluated at a CP -conserving vacuum. Since all the parameters are assumed to be real, CP is conserved so that $v_3 = v_4 = 0$ at the vacuum. But we retain v_3 to derive the mass of the CP -odd scalar according to (2.20). To see contribution from each species, we give the derivatives of the correction to the effective potential from each particle.

A.1 gauge bosons

The contributions to the effective potential is given by (2.8). Its first derivatives at the vacuum are

$$\begin{aligned} \frac{1}{v_1} \frac{\partial \Delta_g V(\mathbf{v})}{\partial v_1} &= \frac{1}{v_2} \frac{\partial \Delta_g V(\mathbf{v})}{\partial v_2} \\ &= 6 \cdot \frac{g_2^2}{2} \frac{m_W^2(\mathbf{v})}{32\pi^2} \left(\log \frac{m_W^2(\mathbf{v})}{M_{\text{ren}}^2} - 1 \right) + 3 \cdot \frac{g_2^2 + g_1^2}{2} \frac{m_Z^2(\mathbf{v})}{32\pi^2} \left(\log \frac{m_Z^2(\mathbf{v})}{M_{\text{ren}}^2} - 1 \right). \end{aligned} \quad (\text{A.1})$$

It is straightforward to calculate the second derivatives:

$$v_1 \frac{\partial}{\partial v_1} \left(\frac{1}{v_1} \frac{\partial \Delta_g V(\mathbf{v})}{\partial v_1} \right) = \frac{3 \cos^2 \beta}{8\pi^2 v_0^2} \left[2m_W^4 \log \frac{m_W^2(\mathbf{v})}{M_{\text{ren}}^2} + m_Z^4 \log \frac{m_Z^2(\mathbf{v})}{M_{\text{ren}}^2} \right], \quad (\text{A.2})$$

$$v_2 \frac{\partial}{\partial v_2} \left(\frac{1}{v_2} \frac{\partial \Delta_g V(\mathbf{v})}{\partial v_2} \right) = \frac{3 \sin^2 \beta}{8\pi^2 v_0^2} \left[2m_W^4 \log \frac{m_W^2(\mathbf{v})}{M_{\text{ren}}^2} + m_Z^4 \log \frac{m_Z^2(\mathbf{v})}{M_{\text{ren}}^2} \right], \quad (\text{A.3})$$

$$\frac{\partial^2 \Delta_g V(\mathbf{v})}{\partial v_1 \partial v_2} = \frac{3 \sin \beta \cos \beta}{8\pi^2 v_0^2} \left[2m_W^4 \log \frac{m_W^2(\mathbf{v})}{M_{\text{ren}}^2} + m_Z^4 \log \frac{m_Z^2(\mathbf{v})}{M_{\text{ren}}^2} \right], \quad (\text{A.4})$$

$$\frac{\partial^2 \Delta_g V(\mathbf{v})}{\partial v_3^2} = \frac{1}{v_3} \frac{\partial \Delta_g V(\mathbf{v})}{\partial v_3} = \frac{1}{v_2} \frac{\partial \Delta_g V(\mathbf{v})}{\partial v_2}. \quad (\text{A.5})$$

A.2 top quark

Since the contribution from the top quark (2.9) is independent of v_1 , any derivative with respect to v_1 vanishes.

$$\begin{aligned} \frac{1}{v_1} \frac{\partial \Delta_g V(\mathbf{v})}{\partial v_1} &= 0, \\ \frac{1}{v_2} \frac{\partial \Delta_g V(\mathbf{v})}{\partial v_2} &= \frac{1}{v_3} \frac{\partial \Delta_g V(\mathbf{v})}{\partial v_3} = -12 \cdot y_t^2 \frac{m_t^2(\mathbf{v})}{32\pi^2} \left(\log \frac{m_t^2(\mathbf{v})}{M_{\text{ren}}^2} - 1 \right), \end{aligned} \quad (\text{A.6})$$

and

$$v_1 \frac{\partial}{\partial v_1} \left(\frac{1}{v_1} \frac{\partial \Delta_t V(\mathbf{v})}{\partial v_1} \right) = \frac{\partial^2 \Delta_t V(\mathbf{v})}{\partial v_1 \partial v_2} = 0, \quad (\text{A.7})$$

$$v_2 \frac{\partial}{\partial v_2} \left(\frac{1}{v_2} \frac{\partial \Delta_t V(\mathbf{v})}{\partial v_2} \right) = -12 \cdot \frac{4m_t^4(\mathbf{v})}{v_0^2 \sin^2 \beta} \frac{1}{32\pi^2} \log \frac{m_t^2(\mathbf{v})}{M_{\text{ren}}^2}, \quad (\text{A.8})$$

$$\frac{\partial^2 \Delta_t V(\mathbf{v})}{\partial v_3^2} = \frac{1}{v_2} \frac{\partial \Delta_t V(\mathbf{v})}{\partial v_2}. \quad (\text{A.9})$$

A.3 top squarks

The stop contribution is given by (2.10), in which the mass eigenvalues are

$$m_{\tilde{t}_a}^2(\mathbf{v}) = \frac{m_{\tilde{t}_L}^2 + m_{\tilde{t}_R}^2}{2} + \frac{g_2^2 + g_1^2}{8}(v_1^2 - v_2^2 - v_3^2) + m_t^2(\mathbf{v}) \pm \sqrt{\left(\frac{m_{\tilde{t}_L}^2 - m_{\tilde{t}_R}^2}{2} + \frac{3g_2^2 - 5g_1^2}{24}(v_1^2 - v_2^2 - v_3^2)\right)^2 + \frac{y_t^2}{2}[(\mu v_1 + A_t v_2)^2 + A_t^2 v_3^2]}. \quad (\text{A.10})$$

The first derivatives are given by

$$\frac{1}{v_i} \frac{\partial \Delta_{\tilde{t}} V(\mathbf{v})}{\partial v_i} = 6 \sum_{a=1,2} \frac{1}{v_i} \frac{\partial m_{\tilde{t}_a}^2(\mathbf{v})}{\partial v_i} \frac{m_{\tilde{t}_a}^2(\mathbf{v})}{32\pi^2} \left(\log \frac{m_{\tilde{t}_a}^2(\mathbf{v})}{M_{\text{ren}}^2} - 1 \right), \quad (\text{A.11})$$

where the first derivatives of the stop mass-squared evaluated at the vacuum are

$$\frac{1}{v_1} \frac{\partial m_{\tilde{t}_a}^2}{\partial v_1} = \frac{2m_t^2}{v_0^2 \sin^2 \beta} \left(\frac{m_Z^2 \sin^2 \beta}{2m_t^2} \pm \frac{n_{\tilde{t}}^{(1)}}{R_{\tilde{t}}} \right), \quad (\text{A.12})$$

$$\frac{1}{v_2} \frac{\partial m_{\tilde{t}_a}^2}{\partial v_2} = \frac{2m_t^2}{v_0^2 \sin^2 \beta} \left(1 - \frac{m_Z^2 \sin^2 \beta}{2m_t^2} \pm \frac{n_{\tilde{t}}^{(2)}}{R_{\tilde{t}}} \right), \quad (\text{A.13})$$

$$\frac{1}{v_3} \frac{\partial m_{\tilde{t}_a}^2}{\partial v_3} = \frac{2m_t^2}{v_0^2 \sin^2 \beta} \left(1 - \frac{m_Z^2 \sin^2 \beta}{2m_t^2} \pm \frac{-\frac{8m_W^2 - 5m_Z^2}{6m_t^2} d_{\tilde{t}} \sin^2 \beta + \frac{1}{2} A_t^2}{R_{\tilde{t}}} \right), \quad (\text{A.14})$$

with

$$\begin{aligned} d_{\tilde{t}} &= \frac{m_{\tilde{t}_L}^2 - m_{\tilde{t}_R}^2}{2} + \frac{8m_W^2 - 5m_Z^2}{6} \cos(2\beta), \\ n_{\tilde{t}}^{(1)} &= \frac{8m_W^2 - 5m_Z^2}{6m_t^2} d_{\tilde{t}} \sin^2 \beta + \frac{1}{2} \mu (\mu + A_t \tan \beta), \\ n_{\tilde{t}}^{(2)} &= -\frac{8m_W^2 - 5m_Z^2}{6m_t^2} d_{\tilde{t}} \sin^2 \beta + \frac{1}{2} A_t (\mu \cot \beta + A_t), \\ R_{\tilde{t}} &= \sqrt{d_{\tilde{t}}^2 + m_t^2 (\mu \cot \beta + A_t)^2}. \end{aligned} \quad (\text{A.15})$$

The general expression for the second derivatives is given by

$$\begin{aligned} v_j \frac{\partial}{\partial v_i} \left(\frac{1}{v_j} \frac{\partial \Delta_{\tilde{t}} V(\mathbf{v})}{\partial v_j} \right) &= 6 \sum_{a=1,2} \left[v_j \frac{\partial}{\partial v_i} \left(\frac{1}{v_j} \frac{\partial m_{\tilde{t}_a}^2(\mathbf{v})}{\partial v_j} \right) \frac{m_{\tilde{t}_a}^2(\mathbf{v})}{32\pi^2} \left(\log \frac{m_{\tilde{t}_a}^2(\mathbf{v})}{M_{\text{ren}}^2} - 1 \right) \right. \\ &\quad \left. + \frac{\partial m_{\tilde{t}_a}^2(\mathbf{v})}{\partial v_i} \frac{\partial m_{\tilde{t}_a}^2(\mathbf{v})}{\partial v_j} \frac{1}{32\pi^2} \log \frac{m_{\tilde{t}_a}^2(\mathbf{v})}{M_{\text{ren}}^2} \right] \end{aligned} \quad (\text{A.16})$$

The relevant second derivatives to this expression are

$$v_1 \frac{\partial}{\partial v_1} \left(\frac{1}{v_1} \frac{\partial m_{t_a}^2}{\partial v_1} \right) = \pm \frac{\cos^2 \beta}{v_0^2} \left[\frac{\left(\frac{8m_W^2 - 5m_Z^2}{3} \right)^2 - \frac{\mu A_t m_t^2}{\sin \beta \cos^3 \beta}}{R_{\tilde{t}}} - \frac{\left(n_{\tilde{t}}^{(1)} \right)^2}{R_{\tilde{t}}^3} \right], \quad (\text{A.17})$$

$$v_2 \frac{\partial}{\partial v_2} \left(\frac{1}{v_2} \frac{\partial m_{t_a}^2}{\partial v_2} \right) = \pm \frac{\sin^2 \beta}{v_0^2} \left[\frac{\left(\frac{8m_W^2 - 5m_Z^2}{3} \right)^2 - \frac{\mu A_t m_t^2 \cos \beta}{\sin^5 \beta}}{R_{\tilde{t}}} - \frac{\left(n_{\tilde{t}}^{(2)} \right)^2}{R_{\tilde{t}}^3} \right], \quad (\text{A.18})$$

$$\frac{\partial^2 m_{t_a}^2}{\partial v_1 \partial v_2} = \pm \frac{\sin \beta \cos \beta}{v_0^2} \left[\frac{-\left(\frac{8m_W^2 - 5m_Z^2}{3} \right)^2 + \frac{\mu A_t m_t^2}{\sin^3 \beta \cos \beta}}{R_{\tilde{t}}} - \frac{n_{\tilde{t}}^{(1)} n_{\tilde{t}}^{(2)}}{R_{\tilde{t}}^3} \right], \quad (\text{A.19})$$

$$v_3 \frac{\partial}{\partial v_3} \left(\frac{1}{v_3} \frac{\partial m_{t_a}^2}{\partial v_3} \right) = 0. \quad (\text{A.20})$$

A.4 charginos

The derivatives of (2.11) are evaluated in the same manner as the case of the stop. The mass-squared eigenvalues are

$$m_{\chi_a^\pm}^2(\mathbf{v}) = m_W^2(\mathbf{v}) + \frac{M_2^2 + \mu^2}{2} \pm \sqrt{\left(\frac{M_2^2 - \mu^2}{2} + \frac{g_2^2}{4}(v_1^2 - v_2^2 - v_3^2) \right)^2 + \frac{g_2^2}{2}[(\mu v_1 + M_2 v_2)^2 + M_2^2 v_3^2]}. \quad (\text{A.21})$$

The first derivatives of the corrections to the effective potential is given by a similar expression to (A.11), in which the relevant derivatives of the masses-squared are

$$\frac{1}{v_1} \frac{\partial m_{\chi_a^\pm}^2}{\partial v_1} = \frac{2m_W^2}{v_0^2} \left(1 \pm \frac{n_\chi^{(1)}}{R_\chi} \right), \quad (\text{A.22})$$

$$\frac{1}{v_2} \frac{\partial m_{\chi_a^\pm}^2}{\partial v_2} = \frac{2m_W^2}{v_0^2} \left(1 \pm \frac{n_\chi^{(2)}}{R_\chi} \right), \quad (\text{A.23})$$

$$\frac{1}{v_3} \frac{\partial m_{\chi_a^\pm}^2}{\partial v_3} = \frac{2m_W^2}{v_0^2} \left(1 \pm \frac{\frac{M_2^2 + \mu^2}{2} - m_W^2 \cos(2\beta)}{R_\chi} \right), \quad (\text{A.24})$$

where

$$\begin{aligned} n_\chi^{(1)} &= \frac{M_2^2 + \mu^2}{2} + m_W^2 \cos(2\beta) + \mu M_2 \tan \beta, \\ n_\chi^{(2)} &= \frac{M_2^2 + \mu^2}{2} - m_W^2 \cos(2\beta) + \mu M_2 \cot \beta, \\ R_\chi &= \sqrt{\left(\frac{M_2^2 - \mu^2}{2} + m_W^2 \cos(2\beta) \right)^2 + 2m_W^2 (M_2 \sin \beta + \mu \cos \beta)^2}. \end{aligned} \quad (\text{A.25})$$

The second derivatives have the same form as (A.16) except for the overall coefficient. The relevant second derivatives are given by

$$v_1 \frac{\partial}{\partial v_1} \left(\frac{1}{v_1} \frac{\partial m_{\chi_a^\pm}^2}{\partial v_1} \right) = \pm \frac{2m_W^2}{v_0^2} \left[\frac{2m_W^2 \cos^2 \beta - \mu M_2 \tan \beta}{R_\chi} - \frac{2m_W^2 \left(n_\chi^{(1)} \right)^2 \cos^2 \beta}{R_\chi^3} \right], \quad (\text{A.26})$$

$$v_2 \frac{\partial}{\partial v_2} \left(\frac{1}{v_2} \frac{\partial m_{\chi_a^\pm}^2}{\partial v_2} \right) = \pm \frac{2m_W^2}{v_0^2} \left[\frac{2m_W^2 \sin^2 \beta - \mu M_2 \cot \beta}{R_\chi} - \frac{2m_W^2 \left(n_\chi^{(1)} \right)^2 \sin^2 \beta}{R_\chi^3} \right], \quad (\text{A.27})$$

$$\frac{\partial^2 m_{\chi_a^\pm}^2}{\partial v_1 \partial v_2} = \pm \frac{2m_W^2}{v_0^2} \left[\frac{-2m_W^2 \sin \beta \cos \beta + \mu M_2}{R_\chi} - \frac{2m_W^2 n_\chi^{(1)} n_\chi^{(2)} \sin \beta \cos \beta}{R_\chi^3} \right], \quad (\text{A.28})$$

$$v_3 \frac{\partial}{\partial v_3} \left(\frac{1}{v_3} \frac{\partial m_{\chi_a^\pm}^2}{\partial v_3} \right) = 0. \quad (\text{A.29})$$

A.5 neutralinos

Although the neutralino contribution to the effective potential is given by (2.12) in terms of the mass eigenvalues, it is difficult to work out its derivatives, since the eigenvalues have complicated forms. To avoid this complexity, we return to the original form of the neutralino contribution:

$$\Delta_{\chi^0} V(\mathbf{v}) = \frac{i}{2} \int_k \text{Tr} \log \left[D_{\chi^0}^{-1}(k; \mathbf{v}) \right], \quad (\text{A.30})$$

where $\int_k$ denotes the integral over the Minkowskian momentum, the trace is taken over the index of 4-dimensional internal space and the spinor index, and D_{χ^0} is the four-component Dirac operator defined by

$$D_{\chi^0}^{-1}(k; \mathbf{v}) = \not{k} - M_{\chi^0} \frac{1 - \gamma_5}{2} - M_{\chi^0}^\dagger \frac{1 + \gamma_5}{2}. \quad (\text{A.31})$$

Here the mass matrix M_{χ^0} is defined by (2.17). The first and second derivatives of (A.30) have the forms of

$$\begin{aligned} \frac{\partial \Delta_{\chi^0} V(\mathbf{v})}{\partial v_i} &= \frac{i}{2} \int_k \text{Tr} \left[D_{\chi^0}(k; \mathbf{v}) \frac{\partial D_{\chi^0}^{-1}(k; \mathbf{v})}{\partial v_i} \right], \\ \frac{\partial^2 \Delta_{\chi^0} V(\mathbf{v})}{\partial v_i \partial v_j} &= -\frac{i}{2} \int_k \text{Tr} \left[D_{\chi^0}(k; \mathbf{v}) \frac{\partial D_{\chi^0}^{-1}(k; \mathbf{v})}{\partial v_i} D_{\chi^0}(k; \mathbf{v}) \frac{\partial D_{\chi^0}^{-1}(k; \mathbf{v})}{\partial v_j} \right]. \end{aligned} \quad (\text{A.32})$$

The integrand of the first derivative evaluated at the vacuum have the following compact form:

$$\frac{1}{v_i} \text{Tr} \left[D_{\chi^0}(k; \mathbf{v}) \frac{\partial D_{\chi^0}^{-1}(k; \mathbf{v})}{\partial v_i} \right] = -\frac{2m_Z^2}{v_0^2} \text{Tr} \left[\frac{\not{k} + \mu_i}{k^2 - \mu^2} \frac{D_1(k)}{1 - m_Z^2 D_1(k) D_2(k)} \right], \quad (\text{A.33})$$

where

$$D_1(k) = \frac{\cos^2 \theta_W}{\not{k} - M_2} + \frac{\sin^2 \theta_W}{\not{k} - M_1}, \quad D_2(k) = \frac{\not{k} + \mu \sin(2\beta)}{k^2 - \mu^2}, \quad (\text{A.34})$$

and

$$\mu_1 \equiv \mu \tan \beta, \quad \mu_2 \equiv \mu \cot \beta. \quad (\text{A.35})$$

The integrands of the second derivatives are reduced to

$$\begin{aligned} & \text{Tr} \left[D_{\chi^0}(k; \mathbf{v}) \frac{\partial D_{\chi^0}^{-1}(k; \mathbf{v})}{\partial v_1} D_{\chi^0}(k; \mathbf{v}) \frac{\partial D_{\chi^0}^{-1}(k; \mathbf{v})}{\partial v_1} \right] \\ &= \frac{2m_Z^2}{v_0^2} \text{Tr} \left[\frac{\not{k}}{k^2 - \mu^2} \frac{D_1(k)}{1 - m_Z^2 D_1(k) D_2(k)} \right] \\ & \quad + \frac{4m_Z^4 \cos^2 \beta}{v_0^2} \text{Tr} \left[\left(\frac{\not{k} + \mu \tan \beta}{k^2 - \mu^2} \frac{D_1(k)}{1 - m_Z^2 D_1(k) D_2(k)} \right)^2 \right], \end{aligned} \quad (\text{A.36})$$

$$\begin{aligned} & \text{Tr} \left[D_{\chi^0}(k; \mathbf{v}) \frac{\partial D_{\chi^0}^{-1}(k; \mathbf{v})}{\partial v_2} D_{\chi^0}(k; \mathbf{v}) \frac{\partial D_{\chi^0}^{-1}(k; \mathbf{v})}{\partial v_2} \right] \\ &= \frac{2m_Z^2}{v_0^2} \text{Tr} \left[\frac{\not{k}}{k^2 - \mu^2} \frac{D_1(k)}{1 - m_Z^2 D_1(k) D_2(k)} \right] \\ & \quad + \frac{4m_Z^4 \sin^2 \beta}{v_0^2} \text{Tr} \left[\left(\frac{\not{k} + \mu \cot \beta}{k^2 - \mu^2} \frac{D_1(k)}{1 - m_Z^2 D_1(k) D_2(k)} \right)^2 \right], \end{aligned} \quad (\text{A.37})$$

$$\begin{aligned} & \text{Tr} \left[D_{\chi^0}(k; \mathbf{v}) \frac{\partial D_{\chi^0}^{-1}(k; \mathbf{v})}{\partial v_1} D_{\chi^0}(k; \mathbf{v}) \frac{\partial D_{\chi^0}^{-1}(k; \mathbf{v})}{\partial v_2} \right] \\ &= \frac{2m_Z^2}{v_0^2} \text{Tr} \left[\frac{\mu}{k^2 - \mu^2} \frac{D_1(k)}{1 - m_Z^2 D_1(k) D_2(k)} \right] \\ & \quad + \frac{4m_Z^4 \sin \beta \cos \beta}{v_0^2} \text{Tr} \left[\frac{\not{k} + \mu \tan \beta}{k^2 - \mu^2} \frac{\not{k} + \mu \cot \beta}{k^2 - \mu^2} \left(\frac{D_1(k)}{1 - m_Z^2 D_1(k) D_2(k)} \right)^2 \right], \end{aligned} \quad (\text{A.38})$$

$$\begin{aligned} & \text{Tr} \left[D_{\chi^0}(k; \mathbf{v}) \frac{\partial D_{\chi^0}^{-1}(k; \mathbf{v})}{\partial v_3} D_{\chi^0}(k; \mathbf{v}) \frac{\partial D_{\chi^0}^{-1}(k; \mathbf{v})}{\partial v_3} \right] \\ &= \frac{2m_Z^2}{v_0^2} \text{Tr} \left[\frac{\not{k}}{k^2 - \mu^2} \frac{D_1(k)}{1 - m_Z^2 D_1(k) D_2(k)} \right] \\ & \quad - \frac{4m_Z^4 \cos^2 \beta}{v_0^2} \frac{\mu^2}{(k^2 - \mu^2)^2} \text{Tr} \left[\frac{D_1(k)}{1 - m_Z^2 D_1(k) D_2(k)} \frac{D_1(-k)}{1 - m_Z^2 D_1(-k) D_2(-k)} \right]. \end{aligned} \quad (\text{A.39})$$

For the special case of $M_2 = M_1$ which is extensively investigated in this paper, we have the following formulas for the relevant derivatives to the masses of the neutral Higgs bosons.

$$\begin{aligned}
& \frac{1}{v_i} \frac{\partial \Delta_{\chi^0} V(\mathbf{v})}{\partial v_i} \\
= & \frac{m_Z^2}{4\pi^2 v_0^2} \left\{ -(\mu^2 + m_Z^2) \left(\log \frac{\mu^2 + m_Z^2}{M_{\text{ren}}^2} - 1 \right) + M_2(M_2 + \mu_i) L(M_2^2, \mu^2 + m_Z^2) \right. \\
& + \left(1 + \frac{\mu \sin(2\beta)}{M_2} \right) m_Z^2 \left[- \left(2 + \frac{\mu_i}{M_2} \right) F_1 \left(\frac{\mu}{M_2}, \frac{m_Z}{M_2}, \tan \beta \right) \right. \\
& \quad \left. + 2 \left(1 + \frac{\mu_i}{M_2} \right) F_2 \left(\frac{\mu}{M_2}, \frac{m_Z}{M_2}, \tan \beta \right) \right] \\
& \left. + \left(1 + \frac{\mu \sin(2\beta)}{M_2} \right)^2 \frac{m_Z^4}{M_2^2} \left[F_3 \left(\frac{\mu}{M_2}, \frac{m_Z}{M_2}, \tan \beta \right) - \left(1 + \frac{\mu_i}{M_2} \right) F_4 \left(\frac{\mu}{M_2}, \frac{m_Z}{M_2}, \tan \beta \right) \right] \right\}, \tag{A.40}
\end{aligned}$$

$$\begin{aligned}
& -\frac{1}{v_1} \frac{\partial \Delta_{\chi^0} V(\mathbf{v})}{\partial v_1} + \frac{\partial^2 \Delta_{\chi^0} V(\mathbf{v})}{\partial v_1^2} \\
= & \frac{m_Z^2}{4\pi^2 v_0^2} \left\{ (2m_Z^2 \cos^2 \beta - \mu_1 M_2) L(M_2^2, \mu^2 + m_Z^2) \right. \\
& + \left[\frac{\mu_1}{M_2} \left(1 + \frac{\mu \sin(2\beta)}{M_2} \right) - \frac{\mu^2 + m_Z^2 \cos^2 \beta}{M_2^2} \right] m_Z^2 F_1 \left(\frac{\mu}{M_2}, \frac{m_Z}{M_2}, \tan \beta \right) \\
& + 2 \left(1 + \frac{\mu \sin(2\beta)}{M_2} \right) \left(\frac{2m_Z^2 \cos^2 \beta}{M_2^2} - \frac{\mu_1}{M_2} \right) m_Z^2 F_2 \left(\frac{\mu}{M_2}, \frac{m_Z}{M_2}, \tan \beta \right) \\
& + \left(1 + \frac{\mu \sin(2\beta)}{M_2} \right)^2 \left(\frac{\mu_1}{M_2} - \frac{2m_Z^2 \cos^2 \beta}{M_2^2} \right) \frac{m_Z^4}{M_2^2} F_4 \left(\frac{\mu}{M_2}, \frac{m_Z}{M_2}, \tan \beta \right) \\
& \left. - 4m_Z^2 \cos^2 \beta G_{11} \left(\frac{\mu}{M_2}, \frac{m_Z}{M_2}, \tan \beta \right) \right\}, \tag{A.41}
\end{aligned}$$

$$\begin{aligned}
& -\frac{1}{v_2} \frac{\partial \Delta_{\chi^0} V(\mathbf{v})}{\partial v_2} + \frac{\partial^2 \Delta_{\chi^0} V(\mathbf{v})}{\partial v_2^2} \\
= & \frac{m_Z^2}{4\pi^2 v_0^2} \left\{ (2m_Z^2 \sin^2 \beta - \mu_2 M_2) L(M_2^2, \mu^2 + m_Z^2) \right. \\
& + \left[\frac{\mu_2}{M_2} \left(1 + \frac{\mu \sin(2\beta)}{M_2} \right) - \frac{\mu^2 + m_Z^2 \sin^2 \beta}{M_2^2} \right] m_Z^2 F_1 \left(\frac{\mu}{M_2}, \frac{m_Z}{M_2}, \tan \beta \right) \\
& + 2 \left(1 + \frac{\mu \sin(2\beta)}{M_2} \right) \left(\frac{2m_Z^2 \sin^2 \beta}{M_2^2} - \frac{\mu_2}{M_2} \right) m_Z^2 F_2 \left(\frac{\mu}{M_2}, \frac{m_Z}{M_2}, \tan \beta \right) \\
& + \left(1 + \frac{\mu \sin(2\beta)}{M_2} \right)^2 \left(\frac{\mu_2}{M_2} - \frac{2m_Z^2 \sin^2 \beta}{M_2^2} \right) \frac{m_Z^4}{M_2^2} F_4 \left(\frac{\mu}{M_2}, \frac{m_Z}{M_2}, \tan \beta \right) \\
& \left. - 4m_Z^2 \sin^2 \beta G_{22} \left(\frac{\mu}{M_2}, \frac{m_Z}{M_2}, \tan \beta \right) \right\}, \tag{A.42}
\end{aligned}$$

$$\begin{aligned}
& \frac{\partial^2 \Delta_{\chi^0} V(\mathbf{v})}{\partial v_1 \partial v_2} \\
= & \frac{m_Z^2}{4\pi^2 v_0^2} \left\{ (\mu M_2 + m_Z^2 \sin(2\beta)) L(M_2^2, \mu^2 + m_Z^2) \right. \\
& - \left[\frac{\mu}{M_2} \left(1 + \frac{\mu \sin(2\beta)}{M_2} \right) + \frac{(2\mu^2 + m_Z^2) \sin(2\beta)}{M_2^2} \right] m_Z^2 F_1 \left(\frac{\mu}{M_2}, \frac{m_Z}{M_2}, \tan \beta \right) \\
& + 2 \left(1 + \frac{\mu \sin(2\beta)}{M_2} \right) \left(\frac{\mu}{M_2} + \frac{m_Z^2 \sin(2\beta)}{M_2^2} \right) m_Z^2 F_2 \left(\frac{\mu}{M_2}, \frac{m_Z}{M_2}, \tan \beta \right) \\
& - \left(1 + \frac{\mu \sin(2\beta)}{M_2} \right)^2 \left(\frac{\mu}{M_2} + \frac{m_Z^2 \sin(2\beta)}{M_2^2} \right) \frac{m_Z^4}{M_2^2} F_4 \left(\frac{\mu}{M_2}, \frac{m_Z}{M_2}, \tan \beta \right) \\
& \left. - 2m_Z^2 \sin(2\beta) G_{12} \left(\frac{\mu}{M_2}, \frac{m_Z}{M_2}, \tan \beta \right) \right\}, \tag{A.43}
\end{aligned}$$

$$\begin{aligned}
& - \frac{1}{v_2} \frac{\partial \Delta_{\chi^0} V(\mathbf{v})}{\partial v_2} + \frac{\partial^2 \Delta_{\chi^0} V(\mathbf{v})}{\partial v_3^2} \\
= & \frac{m_Z^2}{4\pi^2 v_0^2} \left\{ -\mu_2 M_2 L(M_2^2, \mu^2 + m_Z^2) + \frac{\mu_2}{M_2} m_Z^2 F_1 \left(\frac{\mu}{M_2}, \frac{m_Z}{M_2}, \tan \beta \right) \right. \\
& - 2 \frac{\mu_2}{M_2} \left(1 + \frac{\mu \sin(2\beta)}{M_2} \right) m_Z^2 F_2 \left(\frac{\mu}{M_2}, \frac{m_Z}{M_2}, \tan \beta \right) \\
& \left. + \frac{\mu_2}{M_2} \left(1 + \frac{\mu \sin(2\beta)}{M_2} \right)^2 \frac{m_Z^4}{M_2^2} F_4 \left(\frac{\mu}{M_2}, \frac{m_Z}{M_2}, \tan \beta \right) \right\}. \tag{A.44}
\end{aligned}$$

Here various functions arising from the momentum integrals are defined by

$$L(m_1^2, m_2^2) = \begin{cases} -\log \frac{m_1^2}{M_{\text{ren}}^2}, & \text{for } m_1^2 = m_2^2 \\ -\frac{m_1^2}{m_1^2 - m_2^2} \log \frac{m_1^2}{M_{\text{ren}}^2} + \frac{m_2^2}{m_1^2 - m_2^2} \log \frac{m_2^2}{M_{\text{ren}}^2} + 1. & \text{for } m_1^2 \neq m_2^2 \end{cases} \tag{A.45}$$

$$F_1(a, b, \tan \beta) = \int_0^\infty dx \frac{x}{x(x + a^2 + b^2)^2 + (x + a^2 - ab^2 \sin(2\beta))^2}, \tag{A.46}$$

$$F_2(a, b, \tan \beta) = \int_0^\infty dx \frac{x}{(x+1) [x(x + a^2 + b^2)^2 + (x + a^2 - ab^2 \sin(2\beta))^2]}, \tag{A.47}$$

$$F_3(a, b, \tan \beta) = \int_0^\infty dx \frac{x}{(x + a^2 + b^2) [x(x + a^2 + b^2)^2 + (x + a^2 - ab^2 \sin(2\beta))^2]}, \tag{A.48}$$

$$F_4(a, b, \tan \beta) = \int_0^\infty dx \frac{x}{(x+1)(x + a^2 + b^2) [x(x + a^2 + b^2)^2 + (x + a^2 - ab^2 \sin(2\beta))^2]}, \tag{A.49}$$

$$G_{ij}(a, b, \tan \beta) = \int_0^\infty dx \frac{(x - a_i a_j)(x + a^2 - ab^2 \sin(2\beta)) + (a_i + a_j)x(x + a^2 + b^2)}{[x(x + a^2 + b^2)^2 + (x + a^2 - ab^2 \sin(2\beta))^2]^2}, \tag{A.50}$$

where $a_i = a \cdot \mu_i / \mu$.
